

# MySQL In the Cloud

Migration, Best Practices, High Availability, Scaling

---

**Peter Zaitsev**

CEO

Percona University, Budapest

May 11<sup>th</sup>, 2017

# Let me start....

---

**With some Questions!**

# Question One

---

**How Many of you are  
running MySQL In the  
Cloud ?**

# Question Two

---

**Are you running it in  
Public Cloud ? Private  
Cloud ? Both ?**

# Question Three ?

---

**Are you using DBaaS  
such as Amazon RDS or  
Google CloudSQL or  
running your own ?**

# Question Four

---

**Are you using Containers  
? (Such as Docker)**

# Lets Cover some Basics

---

# What is “Cloud”

---

**Dynamic Programmable  
Infrastructure**

# Public and Private

---

## Public

- Infrastructure Shared with other Users
- Amazon AWS typical example

## Private

- Infrastructure Private for company
- OpenStack installation typical example

# All of those XaaS

---

## IaaS (Infrastructure as a service)

- Works in Infrastructure level: “Compute”, “Storage”, “Network”
- Examples: AWS EC2, S3, EBS

## DBaaS (Database as a service)

- Provides Database Service (Instances or Clusters) to use
- Examples: Amazon RDS, Google Spanner

## PaaS (Platform as a service)

- Provides full platform for your application development
- Examples: Heroku, Amazon Elastic Beanstalk, OpenShift

# Regions and Availability Zones

---

## Region

- Specifies Geographic Region
- Hierarchy - North America – West – California
- High Latency between Regions
- Complete Isolation

## Availability Zone

- Is located in the region
- Reasonably isolated from each other
- Medium Latency between AZ

# Making it Visual

---

Source: <https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/using-regions-availability-zones.html>

# Top Cloud Providers

---

Google Cloud Platform

# Technologies to be aware of

---

openstack®

kubernetes

OPENSIFT

docker

# Decisions to Make

---

# Should you move to the cloud ?

---

**This is decision you rarely have**

**Programmable infrastructure is the future**

**Virtualization overhead is going down**

**Some clouds providers support Bare Metal**

# Public ? Private ? Hybrid

---

## Public Cloud

- Agility
- Scalability
- Costs
- Small and Medium Businesses

## Private Cloud

- Control
- Costs
- Legacy Integration
- Some Enterprise Companies

## Hybrid Cloud

- Infrastructure using Both
- Can get benefits of both
- At the cost of extra complexity

# Single vendor vs Multi Vendor

---

## Single Vendor

- Use all features vendor has to offer
- Danger of Vendor Lock In

## Multi Vendor

- Have to use “lowest common denominator”
- Avoid Vendor Lock In

# DBaaS

---

## DBaaS (ie Amazon RDS)

- Easier
- Takes off some operational pains
- Less Flexible
- More Expensive
- More Lock-In

## IaaS (ie EC2+EBS+S3)

- Harder to roll your own
- Operations on your own (or your partner)
- More Flexible
- Less Expensive
- Less Lock-In

# Open Source in the Cloud

---

**Open Source Compatible  
is not same as Open  
Source**

# Migration

---

# Keep it Simple

---

**Do not try doing upgrade at the same time as migration**

**Exactly same minor version is optimal**

**Same major version - must**

# Moving to IaaS Cloud

---

**General Practices as in Datacenter Migrations apply**

**Easy to use Binary Backups**

**Slave\_compressed\_protocol or compression in VPN**

**Support utilities may need to be modified for EBS/S3**

# Moving to DBaaS

---

**Need to use database dump to copy**

- Mysqldump
- Mysqlpump
- Mydumper

**Can set external slave (Amazon RDS)**

- CALL mysql.rds\_set\_external\_master

**Monitoring Backup may need revision**

- Do not have direct access to physical box
- Do not have root user

# New With Amazon RDS Aurora

---

Can use Percona  
Xtrabackup's Backup to  
seed the cluster

<http://amzn.to/2pk6lq7>

# Moving from DBaaS

---

Logical Database dump as well

Replication supported for Migration only

Configure Binary Log Retention  
*mysql.rds\_set\_configuration*

# Best Practices

---

# Being Cost Efficient

---

Know your cloud vendor pricing policies

Look beyond “compute” pricing

Best Price/Performance configuration in the cloud is likely to be different

AWS: Reserve Instances

AWS: Spot Instances

# Guarantee versus Burst

---

## Guaranteed

- Performance resource is “guaranteed” to have in worst case scenario
- This is what you can plan for

## Burst

- Performance resource can provide
- Typically not guaranteed
- Typically limited in length to prevent abuse

# Network

---

Understand Application-Database Network Latency

Same AZ Optimal; Same Region Must have

10Gb Network

Understand network “jitter”

Latency is critical for most applications

Bandwidth can be important for dumps and batch job

# CPU

---

**Same whenever you're in the cloud or not**

**MySQL uses single thread for single query**

**Multi-Core gives good scalability for “Web” workloads**

# Memory

---

**Use mainly as a cache**

**Very important for Performance**

# Storage

---

## Instance Local Storage

- May or may not be available
- Not Highly available
- May be inexpensive and high Performance

## Cloud Block Storage

- Reliable
- Remote
- Separately Prices
- EBS on AWS

## File/Object Storage

- Store Files/Objects
- No interactive block level access
- S3 on AWS

# Things to Note

---

**You can't get any combination**

**EBS Performance depends on the instance size**

**Provisioned IOPs for Optimal Performance**

**Glacier storage for old backups**

# Operating System

---

**Consider Cloud Optimized Linux Versions**

**At very least use Recent Linux Versions**

**“Cloud Only” Linux might be inconvenient for development**

# MySQL Version and Configuration

---

**Use Recent Version**

**Do not count on good Defaults**

# DBaaS

---

**There is essentially same systems underneath!**

**Most of same practices Apply**

# DBaaS is not always faster

Source: <https://twindb.com/rds-vs-aurora-vs-ec2-benchmark/>

# High Availability

---

# Your Choices

---

**Roll your own**

**Use DBaaS**

# Things to Consider

---

**You have less control or visibility into the infrastructure**

**Things as IP take –over might not work**

# Load Balancers

---

**Cloud Load Balancer (Elastic Load Balancer at AWS)**

**HAProxy**

**ProxySQL**

# Maintaining copies of Data

---

**MySQL Replication**

**MySQL Group Replication**

**Percona XtraDB Replication (PXC) and Galera**

# Why Percona XtraDB Cluster in the Cloud

---

Read/Write to any node works great with simple load balancers

Automatic Provisioning and Auto Scaling

Can run with local instance storage

Can deploy across multiple AZ

# Scaling

---

# Scalability in the Cloud

---

## “Better”

- Due to cloud optimized options like Amazon Aurora

## “Worse”

- Due to restricted hardware choices

# Scaling How

---

## Scale Up

- Vertical Scaling
- Scale with the Hardware Size – CPUs, Memory, Storage

## Scale Out

- Horizontal Scaling
- Scale by adding nodes

# Bad reputation of Scaling Up... but

---

**Reasonable  
commodity  
MySQL  
Server Can  
handle**

- 3-5TB database size
- 100K+ queries/sec
- 5M+ rows read/sec
- 100K rows modified/sec

# Scaling What ?

---

**Reads**

**Writes**

**Data Size**

# Scaling Reads

---

Replication

Caching

Moving some load from MySQL

# Scaling Writes

---

New MySQL Versions

Parallel Replication

TokuDB

Functional Partitioning

Sharding

# New in Sharding

---

ProxySQL

Vitess

# Scaling Data Size

---

Functional Partitioning and Sharding

Data Archiving

TokuDB for Compression

Often Operations drive this needs not App Performance

**Database Performance Matters**
